Preliminaries

Black-box evasion attacks

Black-box attacks advancing rapidly [1,2]

... but efficiency depends on what is API ... whether is targeted attack

Many realistic APIs are restrictive

- Scores for a small subset of all classes
 - Partial Information
- Existing targeted attacks inefficient or ineffective

Query-only methods: Natural Evolution Strategies

Case study on NES [1, 2]:

- Most effective query-only method for targeted adversarial example crafting for such partial information APIs
- Start / goal image distinction

For-loop with three phases:

- Increase pseudo-log-likelihood via NES
- Line search for decreasing perturbation
- Update or backtrack (reset search)

<pre>191 for i in range(max_iters): 203</pre>	
<pre>proposed_adv = adv - is_targeted * current_lr * np.sign(g) prop_de = 0.0 while current_lr >= args.min_lr: # PARTIAL INFORMATION ONLY if k < NUM_LABELS: proposed_epsilon = max(epsilon - prop_de, goal_epsilon) # GENERAL LINE SEARCH proposed_adv = adv - is_targeted * current_lr * np.sign(g) proposed_adv = np.clip(proposed_adv, lower, upper) if robust_in_top_k(target_class, proposed_adv, k): adv = proposed_adv epsilon = max(epsilon - prop_de/args.conservative, goal_epsilon else: if prop_de < 2e-3: prop_de = 0 current_lr = max_lr prop_de = 0 current_lr = max_lr print("[log] backtracking eps to %3f" % (epsilon-prop_de,) # GRADIENT ESTIMATION EVAL def get_grad(pt, spd, bs): </pre>

Targeted attacks on restrictive APIs

Query-only methods:

- High effectiveness, any DNN attackable
- Inefficient: requires 1000s 10,000s queries per sample on restrictive APIs

Transferability ensemble methods [1,2]

- Efficient: first query may already succeed
- Ineffective: success rate is low
- Case study on MIFGSM

What can the adversary do to make targeted evasion more efficient while retaining effectiveness?

"We notice that targeted attacks have little transferability ... it's hard ... for the ImageNet dataset."

[1] Liu et al. Delving into transferable adversarial attacks. ICLR'17

[2] Dong et al. Boosting adversarial attacks with momentum. CVPR'18 NIPS adversarial attack competition winners

[3] dongvp13/Targeted-Adversarial-Attack https://github.com/dongvp13/Targeted-Adversarial-Attack)

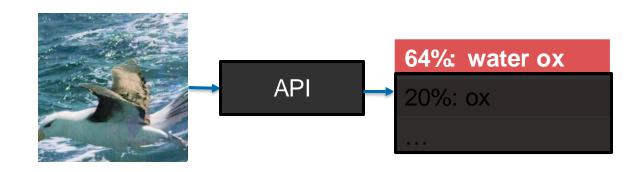

Adversary model

Minimum distance adversarial examples

- Up to 5% mod. (12.8/255) on L_{∞} -norm [1]
- Partial information on API outputs (label+prob.), API access black-box

Evaluation

- 100 images, adapted from [2]:
 - Also includes start images
- Evaluation on ImageNet classifiers:
 - ResNet-101/152, VGG16, Inception v3
- Realistically adversary has access to 10s of surrogate models

6

[1] <u>Ilyas et al. Black-box adversarial attacks with limited information and queries. ICML'18</u>.

Baseline results

	Ensemble transferability	Query-only (max 100,000 queries)
Inception v3	12% : 1	88%: 44,158
ResNet-101	47%: 1	89%: 32,864
VGG16	47%: 1	94%: 28,875
ResNet-152	58%: 1	91%: 34,689

Success rate: mean queries

Adversary has large ensemble with 10/11 components

• Targeted transferability between 47% and 58%

Transferability worst on Inception v3

• Resizing operation from 224 \rightarrow 299 pixels, functions as a defense [1]

Basic agility

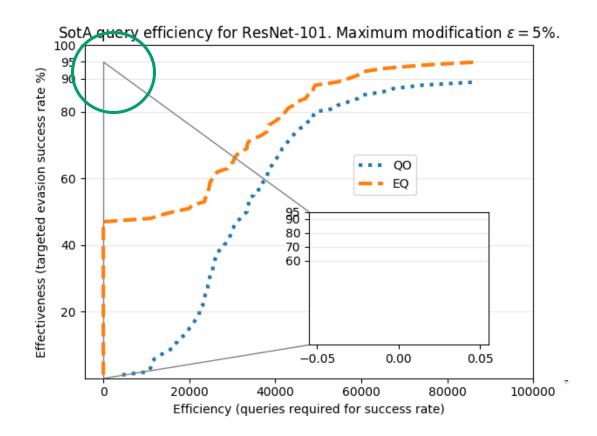

We investigate agile adversaries:

• Can combine methods to reduce queries

Basic agile adversary:

- Ensemble method, then query-only: EQ
- Improves efficiency and effectiveness

Agile adversary can improve efficiency / effectiveness

Improved efficiency / effectiveness

Can we improve efficiency / effectiveness trade-off by designing a new type of attack?

- 1. Take [1] work as a starting point, maintain start / goal image distinction as in [1]
 - Benefits for effectiveness?
- 2. Replace NES with ensemble-based gradient [2]
 - NES [1] perturbation calculation requires ~ 100 queries per sample
- 3. Avoid queries from line search
 - Unnecessary if ensemble gradient close to API model's

PRISM: Partial Information Substitute Model Attack

^{[1] &}lt;u>Ilyas et al. Black-box adversarial attacks with limited information and queries. ICML'18.</u>

^[2] Liu et al. Delving into transferable adversarial attacks. ICLR'17

^[3] Dong et al. Boosting adversarial attacks with momentum, CVPR'18

PRISM: variants and performance

PRISM and **PRISM**_R

- Use all ensemble components or random subset for gradient calculation
- More effective than Ensemble alone
- Require more queries, but can increase effectiveness over regular ensemble-use

Table 5: Effectiveness of black-box evasion methods, *success rate* and *median* number of queries required for success.

	Up to 1000 queries						
	Ensemble	PRISM	PRISM _R	QUERY-ONLY			
IncV3	26%: 2	69%: 11	75%: 14	0%: -			
RN101	83%: 1	88%: 8	93%: 12	0%: -			
VGG16	82%: 1	89%: 10	90%: 13	0%: -			
RN152	84%: 1	95%: 8	96%: 11	0%: -			

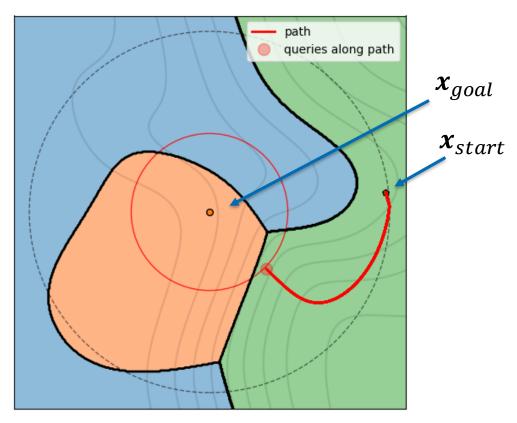

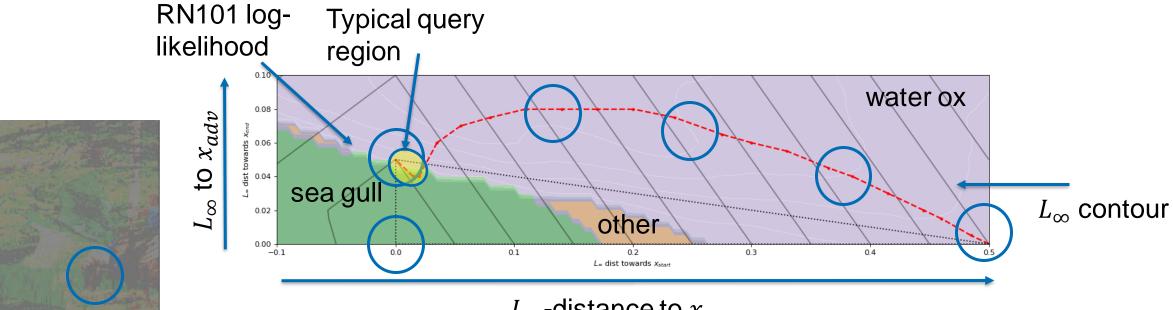

Illustration on PRISM Start from same-class start image

L_{∞} -distance to x_{start}

 x_{goal}

Localized perturbations

x_{start}

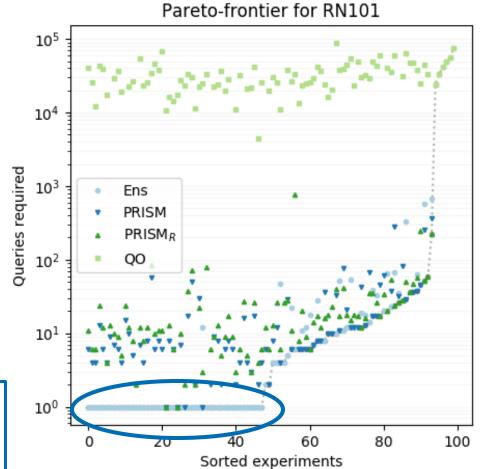

Pareto-efficiency

Given the same task, which methods are most efficient?

Upwards trend:

- Some experiments are harder than others
 - Larger number of min-queries to succeed
- Transferability works in many cases
 - Similarity between surrogates and victim (next slide)

Impact of ensemble size

Number of components.	1	2	3	4	5	6	7	8	9	10
Target model	IncV3									
added model to ens.	DN201	RN101	RN50	DN169	DN121	RN34	RN18	VGG11	SN1.1	SN1.0
Ensemble (1 query)	2%:1	4%: 1	5%: 1	6%: 1	6%: 1	8%: 1	10%: 1	12%: 1	12%: 1	12%: 1
Ensemble (up to 1000 queries)	4%:9	6%: 1	7%: 1	10%: 1	13%: 2	14%: 1	18%: 1	24%: 1	23%: 1	26%: 2
PRISM (up to 1000 queries)	2%: 89	6%: 60	12%: 28	16%: 27	26%: 14	41%: 15	54%: 12	60% 10	62%: 9	69%: 11
Target model	RN101									
added model to ens.	DN201	RN50	DN169	DN121	RN34	VGG16	RN18	VGG11	SN1.1	SN1.0
Ensemble (1 query)	4%: 1	11%: 1	14%: 1	21%: 1	34%: 1	34%: 1	39%: 1	45%: 1	44%: 1	47%: 1
Ensemble (up to 1000 queries)	7%: 1	29%: 8	35%: 3	43%: 2	59%: 1	62%: 1	74%: 1	76%: 1	78%: 1	83%: 1
PRISM (up to 1000 queries)	7%: 84	34%: 29	49%: 26	56%: 16	69% : 14	69%: 12	83%: 8	85%: 8	87%: 9	88%: 8
Target model					VG	G16				
added model to ens.	DN201	RN101	RN50	DN169	DN121	RN34	RN18	VGG11	SN1.1	SN1.0
Ensemble (1 query)	1%: 1	3%: 1	3%: 1	6%: 1	13%: 1	13%: 1	21%: 1	41%:1	42%: 1	47%: 1
Ensemble (up to 1000 queries)	6%: 11	9%: 87	13%: 17	20%: 10	26%: 1	34%: 5	44%: 2	75%: 1	80%: 1	82%: 1
PRISM (up to 1000 queries)	3%: 248	7%: 77	15%: 52	27%: 34	32%: 22	38%: 21	54%: 17	85%: 12	86%: 11	86%: 10

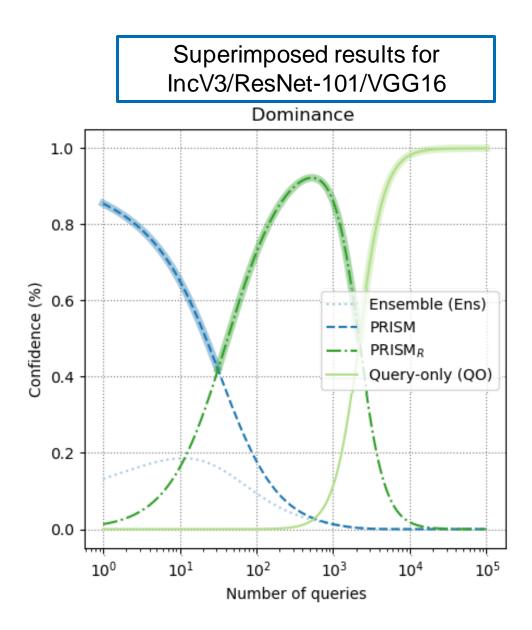

Dominance

Given number of minimum queries, can we prescribe when methods perform better than others?

• Enables efficient strategy determination

Example efficient strategy:

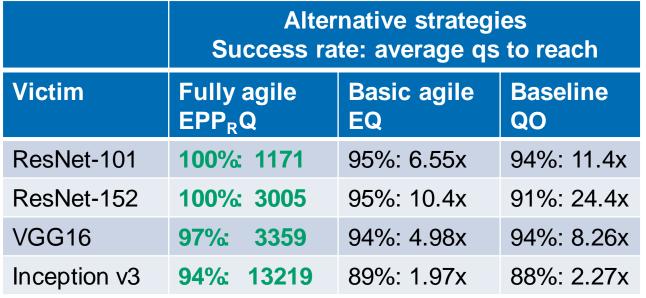

- Ens: 0—1
- PRISM: 1—50
- PRISM_R: 50 3000
- Query-only: 3000+
 > EPP_RQ

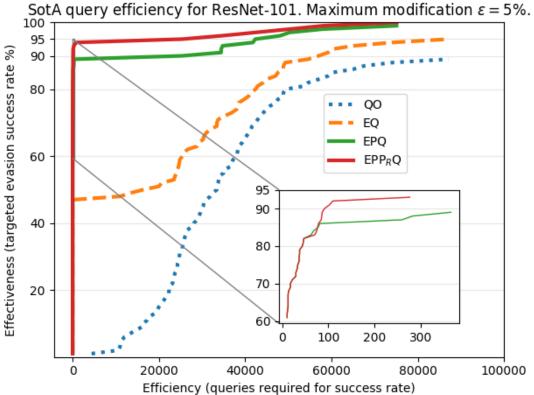

Fully agile attacker

Fully agile adversary EPP_RQ:

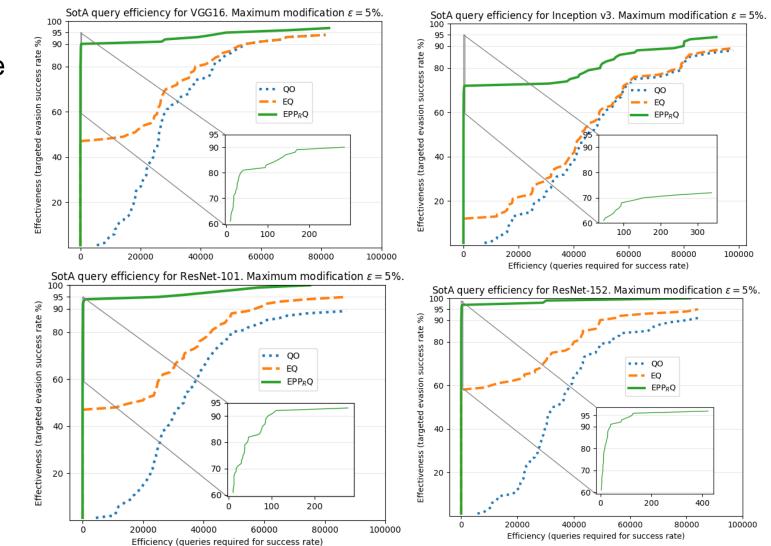

- Effectiveness: +3% to +13%
- Query-efficiency: 1.97x to 24.4x less (average)

Different victim APIs (ImageNet)

- Most efficient when surrogate models available of similar architecture
 - ResNet-101 and ResNet-152
- Typically 2—3 orders faster than query-only alone

Case study: realistic APIs

 $PRISM / PRISM_R$ effective against real APIs

- Reduce number of queries for one example from ~20,000 [1] to ~400—1000
- Example as in [1]

• Demo:

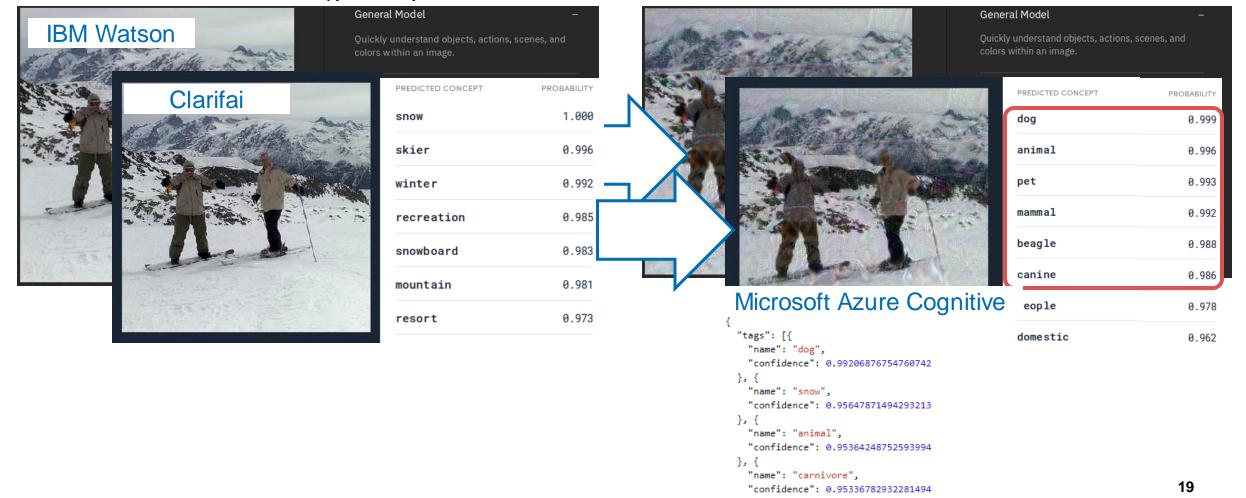

Canidae	92%
Dog	91%
Pointer	72%
Snow	69%
Carnivore	67%
Hunting Dog	66%
Dog Breed	65%
Boxer	60%

Realistic APIs

Same PRISM / PRISM_R examples transfer across all tested APIs

}],

What can the adversary do to make targeted evasion more efficient while retaining effectiveness?

Combine availability of large ensembles + partial-information access to victim API (**PRISM**)

and

analyze and switch through different methods (adversary agility)

 \rightarrow find adversarial examples efficiently and effectively
